

open()

Open a file (creates a file object).

```
1 file = open("example.txt", "r")  
2 print(file.read())  
3 file.close()
```

read()

Read the entire file content.

```
1 with open("example.txt", "r") as f:  
2     data = f.read()  
3     print(data)
```

readline() / readlines()

Read one line or all lines as a list.

```
1  with open("example.txt", "r") as f:  
2      print(f.readline())  
3      # first line  
4      print(f.readlines())  
5      # list of all lines
```

write()

Write text to a file (overwrites existing content).

```
1 with open("example.txt", "w") as f:  
2     f.write("Hello, Python!")
```

append mode ('a')

Add new content without deleting existing data.

```
1 with open("example.txt", "a") as f:  
2     f.write("\nAppended text here.")
```

check if a file exists

Use `os.path.exists()` before opening.

```
1  import os
2  if os.path.exists("example.txt"):
3      print("File found!")
4  else:
5      print("File not found!")
```

delete a file

Use `os.remove()` to delete files safely.

```
1  import os
2  if os.path.exists("old.txt"):
3      os.remove("old.txt")
```

with statement

Automatically close files

```
1  with open("example.txt") as f:  
2      |      data = f.read()  
3      # File closes automatically
```
